# FORECASTING PRINCIPLES AND PRACTICE

# 3. Time series decomposition

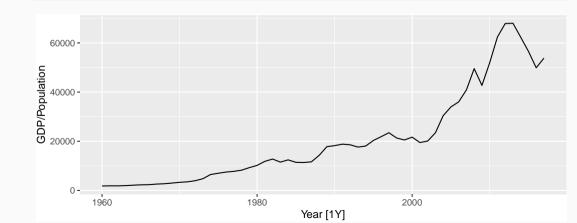

3.1 Transformations and adjustments
OTexts.org/fpp3/

## Per capita adjustments

```
global_economy |>
  filter(Country == "Australia") |>
  autoplot(GDP)
  1.5e+12 -
  1.0e+12 -
  5.0e+11 -
  0.0e+00 -
                                                                   2000
           1960
                                       1980
                                                 Year [1Y]
```

## Per capita adjustments

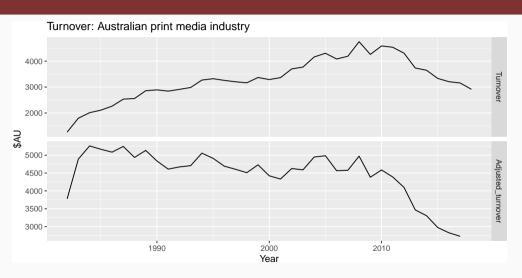

```
global_economy |>
  filter(Country == "Australia") |>
  autoplot(GDP / Population)
```

## Inflation adjustments

```
print retail <- aus retail |>
 filter(Industry == "Newspaper and book retailing") |>
 group_by(Industry) |>
 index by(Year = year(Month)) |>
  summarise(Turnover = sum(Turnover))
aus_economy <- global_economy |>
 filter(Code == "AUS")
print retail |>
 left_join(aus_economy, by = "Year") |>
 mutate(Adjusted_turnover = Turnover / CPI * 100) |>
 pivot_longer(c(Turnover, Adjusted_turnover), values_to = "Turnover") |>
 mutate(name = factor(name, levels = c("Turnover", "Adjusted turnover"))) |>
 ggplot(aes(x = Year, y = Turnover)) +
 geom_line() +
 facet_grid(name ~ ., scales = "free_v") +
 labs(title = "Turnover: Australian print media industry", y = "$AU")
```

## **Inflation adjustments**

If the data show different variation at different levels of the series, then a transformation can be useful.

If the data show different variation at different levels of the series, then a transformation can be useful.

Denote original observations as  $y_1, \ldots, y_T$  and transformed observations as  $w_1, \ldots, w_T$ .

If the data show different variation at different levels of the series, then a transformation can be useful.

Denote original observations as  $y_1, \ldots, y_T$  and transformed observations as  $w_1, \ldots, w_T$ .

#### Mathematical transformations for stabilizing variation

Square root 
$$w_t = \sqrt{y_t}$$

Cube root 
$$w_t = \sqrt[3]{y_t}$$
 Increasing

Logarithm 
$$w_t = \log(y_t)$$
 strength

If the data show different variation at different levels of the series, then a transformation can be useful.

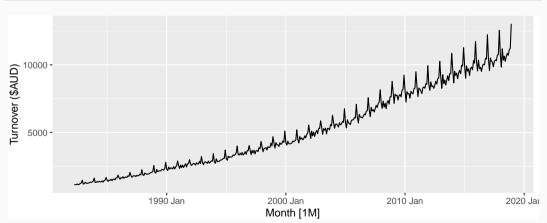

Denote original observations as  $y_1, \ldots, y_T$  and transformed observations as  $w_1, \ldots, w_T$ .

#### Mathematical transformations for stabilizing variation

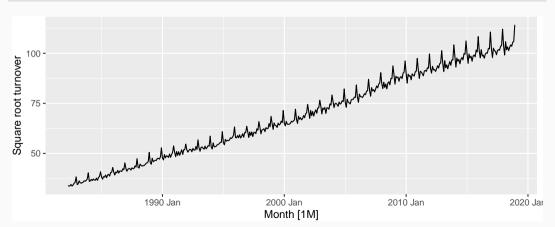

Square root 
$$w_t = \sqrt{y_t}$$
  $\downarrow$  Cube root  $w_t = \sqrt[3]{y_t}$  Increasing Logarithm  $w_t = \log(y_t)$  strength

Logarithms, in particular, are useful because they are more interpretable: changes in a log value are **relative (percent) changes on the original scale**.

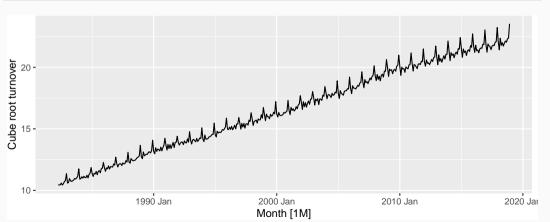

```
food <- aus_retail |>
  filter(Industry == "Food retailing") |>
  summarise(Turnover = sum(Turnover))
```

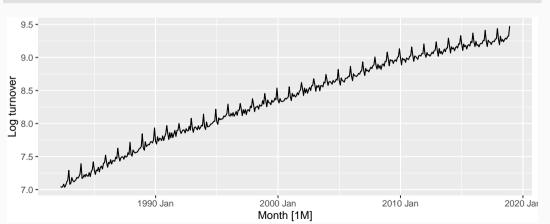

```
food |> autoplot(sqrt(Turnover)) +
  labs(y = "Square root turnover")
```

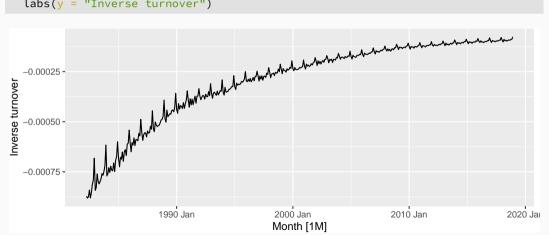

```
food |> autoplot(Turnover^(1 / 3)) +
  labs(y = "Cube root turnover")
```

```
food |> autoplot(log(Turnover)) +
  labs(y = "Log turnover")
```

```
food |> autoplot(-1 / Turnover) +
  labs(y = "Inverse turnover")
```

Each of these transformations is close to a member of the family of

$$w_t = \begin{cases} \log(y_t), & \lambda = 0; \\ (sign(y_t)|y_t|^{\lambda} - 1)/\lambda, & \lambda \neq 0. \end{cases}$$

Each of these transformations is close to a member of the family of

$$w_t = \begin{cases} \log(y_t), & \lambda = 0; \\ (sign(y_t)|y_t|^{\lambda} - 1)/\lambda, & \lambda \neq 0. \end{cases}$$

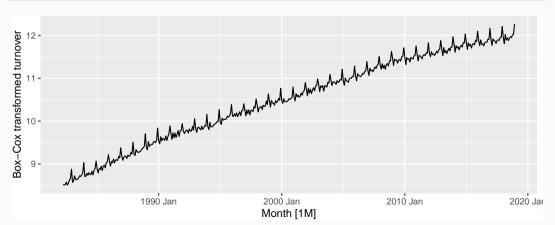

- $\blacksquare$  Actually the Bickel-Doksum transformation (allowing for  $y_t < 0$ )
- $\lambda$  = 1: (No substantive transformation)
- $\lambda = \frac{1}{2}$ : (Square root plus linear transformation)
- $\lambda$  = 0: (Natural logarithm)
- $\lambda = -1$ : (Inverse plus 1)

```
food |>
  features(Turnover, features = guerrero)
```

```
## # A tibble: 1 x 1
## lambda_guerrero
## <dbl>
## 1 0.0895
```

- This attempts to balance the seasonal fluctuations and random variation across the series.
- Always check the results.
- $lue{}$  A low value of  $\lambda$  can give extremely large prediction intervals.

```
food |> autoplot(box_cox(Turnover, 0.0524)) +
  labs(y = "Box-Cox transformed turnover")
```

#### **Transformations**

- Often no transformation needed.
- Simple transformations are easier to explain and work well enough.
- Transformations can have very large effect on PI.
- If some data are zero or negative, then use  $\lambda > 0$ .
- log1p() can also be useful for data with zeros.
- Choosing logs is a simple way to force forecasts to be positive
- Transformations must be reversed to obtain forecasts on the original scale. (Handled automatically by fable.)
